# SUMMARY

## **Australian Fairy Tern (*Sternula nereis nereis*)**

**Family:** Laridae

### **Current status of taxon:**

*Environment Protection and Biodiversity Conservation Act 1999* (Cwlth): Vulnerable

*Threatened Species Protection Act 1995* (Tas): Vulnerable

*Flora and Fauna Guarantee Act 1988* (Vic): Threatened

*National Parks and Wildlife Act 1972* (SA): Endangered

*Biodiversity Conservation Act 2016* (WA): Vulnerable

IUCN Red List of Threatened Species: Vulnerable

### **Distribution and habitat:**

Australian Fairy Terns occur along the southern Australian coast from south of the Dampier archipelago Western Australia east to Botany Bay, New South Wales including Tasmania. The Great Australian Bight forms a gap in distribution between western and eastern subpopulations (Higgins and Davies 1996), and there are now substantial gaps between breeding colonies in eastern Australia, especially around the Victorian coastline (Garnett et al. 2011). Australian Fairy Terns utilise a variety of habitats including offshore, estuarine, lacustrine (lake) islands, wetlands, beaches and sand spits (TSSC 2011).

### **Recovery Plan Vision, Objective, and Strategies:**

#### Long-term Vision

The Australian Fairy Tern population has increased in size to such an extent that the species no longer qualifies for listing as threatened under any of the *Environment Protection and Biodiversity Conservation Act 1999* listing criteria.

#### Recovery Plan Objective

By 2030, sustain a positive population trend in the number of mature individuals of the Australian Fairy Tern in both the eastern and western subpopulations compared to 2020. This will be achieved by implementing the actions set out in this Recovery Plan that minimise threats while protecting the species' habitat throughout its range, generating new knowledge to guide recovery and increasing public awareness.

#### Strategies to achieve objectives

1. Manage and protect known Australian Fairy Tern breeding populations at the landscape scale.
2. Develop and apply techniques to measure changes in population trajectory in order to measure the success of recovery actions.
3. Reduce, or eliminate threats at breeding, non-breeding and foraging sites.
4. Improve understanding of breeding, non-breeding and foraging ecology in order to better target management actions and habitat restoration.
5. Engage community stakeholders in Australian Fairy Tern conservation.
6. Coordinate, review and report on recovery process.

**Criteria for success:**

This recovery plan will be deemed successful if, within 10 years, all of the following have been achieved:

- The Australian Fairy Tern population trajectory is positive compared to 2020 baseline.
- Understanding of the species' ecology has increased, in particular knowledge of breeding biology, movement patterns, habitat use, post-breeding dispersal and survival rates.
- There is increased participation by key stakeholders and the public in recovery efforts and monitoring.

**Recovery team:**

Recovery teams provide advice and assist in coordinating actions described in recovery plans. They include representatives from organisations with a direct interest in the recovery of the species, including those involved in funding and those participating in actions that support the recovery of the species. The Australian Fairy Tern Recovery Team has the responsibility of providing advice, coordinating and directing the implementation of the recovery actions outlined in this recovery plan. The membership of the Recovery Team includes individuals with relevant government agencies, non-government organisations and expertise from independent researchers and community groups.

# INTRODUCTION

This document constitutes the *National Recovery Plan for the Australian Fairy Tern*. The plan considers the conservation requirements of the species across its range and identifies the actions to be taken to ensure the species' long-term viability in nature, and the parties that will undertake those actions. The recovery plan is the first national plan to be developed for the Australian Fairy Tern.

The Australian Fairy Tern is listed as vulnerable under the *Environment Protection and Biodiversity Conservation Act 1999* (Cwlth) (EPBC Act) as there are less than 9,000 mature individuals remaining and the total population has undergone a substantial decline of approximately 24 per cent over the past three generations, or 33 years (TSSC 2011). This decline is expected to continue at a substantial rate over the next three generations, as there is no evidence that the threats affecting this species are abating (TSSC 2011).

Australian Fairy Terns utilise a variety of habitats including offshore, estuarine or lacustrine (lake) islands, wetlands, beaches and sand spits. The subspecies migrates within southern and mid-west Western Australia and possibly Tasmania, where they are seen less frequently during the winter months. The Tasmanian and Victorian population may form a single population. The species is more sedentary in the north of Western Australia and in South Australia (Hill et al. 1988). Australian Fairy Terns nest above the high water mark often in clear view of the water and on sites where the substrate is sandy and the vegetation low and sparse. Nests typically consist of a shallow scrape in the sand which is often lined with small shells and vegetation. While a proportion of the population breeds on islands, there are many nesting sites which occur in coastal areas highly accessible to the public and of variable tenure.

Accompanying Species Profile and Threats Database (SPRAT) pages provide background information on the biology, population status and threats to the Australian Fairy Tern. SPRAT pages are available from: <http://www.environment.gov.au/cgibin/sprat/public/sprat.pl>.

## 2.1 Conservation Status

The Australian Fairy Tern is listed as threatened under the Commonwealth *Environment Protection and Biodiversity Conservation Act 1999* (EPBC Act), and in all parts of its range, except New South Wales. This species is classified as Vulnerable under the EPBC Act owing to recent declines over much of its breeding range. Predation by introduced species, disturbance and inappropriate water level management are thought to have contributed most to this decline. However, data is patchy, and a clarification of trends in its strongholds may lead to its status being revised.

**Table 1:** National and state conservation status of the Australian Fairy Tern

Legislation	Conservation Status
<i>Environment Protection and Biodiversity Conservation Act 1999</i> (EPBC Act)	Vulnerable
<i>Threatened Species Protection Act 1995</i> (Tasmania)	Vulnerable
<i>Flora and Fauna Guarantee Act 1988</i> (Victoria)	Threatened
<i>National Parks and Wildlife Act 1972</i> (South Australia)	Endangered
<i>Biodiversity Conservation Act 2016</i> (Western Australia)	Vulnerable
<i>Biodiversity Conservation Act 2016</i> (New South Wales)	Not listed

## 2.2 Taxonomy

The Australian Fairy Tern is conventionally accepted as *Sternula nereis nereis* (AFD 2019). Paton and Rogers (2009) suggested that there are two subspecies on mainland Australia, *S. n. nereis* in the south-east and *S. n. hornii* in the south-west, although key authorities only recognise *S. n. nereis* in Australia (Christidis and Boles 2008; Garnett et al. 2011; AFD 2019).

The distribution of the Fairy Tern (*Sternula nereis*) is limited to Australasia, including Australia, New Zealand and New Caledonia (Hansen 2006; Dunlop 2018). Three subspecies have been identified based on phenotypic, genotypic and geographic differences. The New Zealand Fairy Tern (*S. n. davise*) is listed as Nationally Critical under the New Zealand Threat Classification System (Hitchmough et al. 2005; Hansen 2006). The New Caledonian Fairy Tern (*S. n. exsul*) has approximately 200 - 400 breeding pairs (Barre et al. 2011), and has recently been recorded in the Swain Reefs, southern Great Barrier Reef, and islands in the Coral Sea Territory suggesting regular movements of over 1,200 km (Carter and Mustoe 2007; Garnett et al. 2011).

Genetic differences were detected between Australian Fairy Terns in Western Australia and south-eastern Australia, however, these were not sufficient to merit treatment as separate sub-species (Dunlop 2018). The highest genetic diversity was found in the largest population in Western Australia (Baling and Brunton 2005), suggesting that this region was the source for the smaller breeding groups found in south-eastern Australia. The low genetic diversity in the satellite populations in New Zealand and New Caledonia probably reflect the genomes of a small number of founders (Dunlop 2018).

## 2.3 Species description

A small piscivorous (fish-eating) bird, the Australian Fairy Tern is approximately 22 – 27 cm in length, 70 g in weight and has a wingspan of 44 – 53 cm (Higgins and Davies 1996). The Australian Fairy Tern is bulky and round bodied (Simpson and Day 2004). The species is very similar to Little Tern (*S. albifrons*) except the upperwings are more uniformly grey and the forehead is steep.

The breeding plumage of both sexes is pale grey-white, with a black crown, nape, ear coverts and patch in front of the eyes (square to round in shape). The forehead is white and the bill is orange-yellow (Higgins and Davies 1996). Legs are dull yellow and the iris is dark brown (Lindsey 1986).

There is also little sexual dimorphism in non-breeding plumage, with a black bill and a more mottled appearance to the crown (Higgins and Davies 1996). Outer primary feathers are also less contrasting with no dark shoulder bar (Simpson and Day 2004).

Immature birds have blackish legs and bills (Lindsey 1986). The crown is streaked dusky and buff with a dark ear patch. The outer wing is dark greyish and the inner wing is pale grey and white (Simpson and Day 2004).

The species is gregarious and often found in flocks of 40 to several hundred birds. However, birds are also seen singly or in pairs (Higgins and Davies 1996).

## 2.4 Species distribution in Australia

The Australian Fairy Tern occurs in coastal southern Australia from the Montebello Islands of the Pilbara, Western Australia east to Botany Bay, New South Wales including Tasmania. The Great Australian Bight forms a gap in distribution between western and eastern subpopulations (Higgins and Davies 1996), and there are now substantial gaps between breeding colonies in eastern Australia, especially around the Victorian coastline. The species has been recorded in Queensland but is considered to be a vagrant or an occasional visitor. These Fairy Terns from southeast Queensland were not subspecifically identified and the occurrence in southeast Queensland could be either an extension

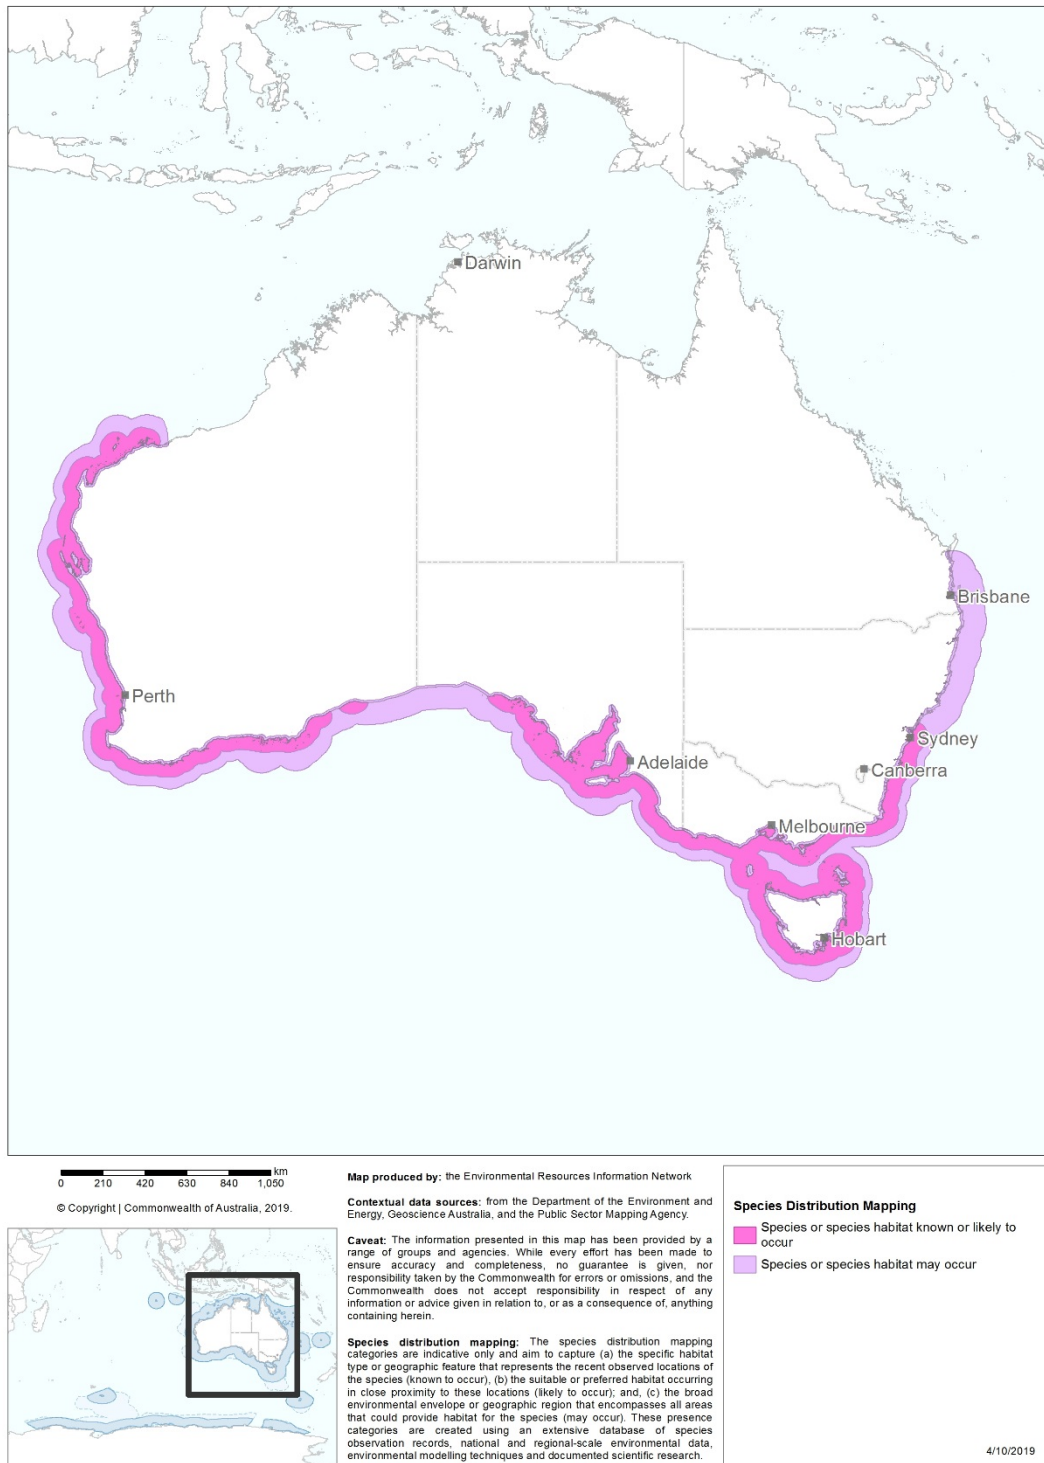

of northern limit of the distribution of the nominate (*S. n. neries*) or more likely New Caledonian Fairy Tern.

Within Western Australia there appear to be two subpopulations (Dunlop 2018). One is sedentary and based along the Pilbara and upper Gascoyne coasts from Exmouth Gulf to the Dampier Archipelago, including Barrow Island and the Monte Bello and Lowendal Archipelagos. These Australian Fairy Terns nest from late July to late September (Johnstone and Storr 1998, Dunlop 2018). A second, migratory subpopulation disperses south along the coastline from Shark Bay (Burbidge and Fuller 2000) to breed between Houtman Abrolhos Islands to the Recherche Archipelago between September and May, with active breeding flocks appearing at various locations between October and February (Johnstone and Storr 1998). At present it is not clear what controls the recruitment of individuals to these over-lapping subpopulations (Dunlop 2018). It is also currently not known at what scale local breeding groups (which probably establish colonies at a number of sites) represent conservation management units within the migratory subpopulation (Dunlop 2018).

Biologically Important Areas for this species occur in Australian Marine Parks, particularly in the South-west and North-west Marine Parks Networks. Under statutory management plans, Australian Marine Parks are managed for the protection and conservation of biodiversity and other natural, cultural and heritage values of marine parks, including protected species. More information about Australian Marine Parks can be found [here](#).

**Figure 1:** Modelled distribution of the Australian Fairy Tern

## 2.5 Population trends

The total population in Australia is estimated at less than 9,000 mature individuals. The largest population of 6,000 in Western Australia is believed to be stable. In eastern Australia there have been rapid declines: there are currently about 180 – 300 pairs in South Australia (2009-2010), 200 – 250 pairs in Tasmania, 6 – 70 pairs in Victoria and 12 – 40 pairs in NSW (2009-2010), where numbers are thought to have increased (NSW National Parks and Wildlife Service 2003; Garnett et al. 2011; Adams et al. 2019).

In South Australia, numbers in the South Lagoon of the Coorong declined from 1,330 individuals in 1985 to 150 – 300 in 2000-2007, an 82 per cent decline (Paton and Rogers 2009). Only 357 individuals were counted during the annual census of waterbirds in the Coorong in January 2018. This result is less than in January 2015 and 2016 and is only a little over half of the birds that were using the Coorong in the early 2000s (Paton and Paton 2018). Australian Fairy Tern numbers have continued to decline in the Coorong where 315 individuals were detected in January 2019 (Paton et al. 2019). Elsewhere in South Australia, the species disappeared from the Fleurieu Peninsula in the late 1970s and around Kangaroo Island in the early 1990s. Breeding populations in Gulf St Vincent, Spencer Gulf and near Beachport are very small with low breeding success (Garnett et al. 2011).

In Victoria, the number of breeding pairs at French Island in Western Port Bay fell from a peak of 108 in 1993 to an average of 21 for the decade 1996-2005 (Garnett et al. 2001). Historically, colonies of over 50 breeding pairs were observed within Western Port and Port Phillip Bay but numbers began to decline in the late 1980s (Adams et al. 2019). There are currently few records documenting successful breeding attempts over the last decade within the two bays and it is thought that breeding success is poor (Adams et al. 2019). Approximately 54 adults comprising three colonies were observed within Western Port and Port Phillip Bays during the 2016/17 breeding season. Only one breeding colony of 30-40 adults was observed during the 2017/18 breeding season while no breeding colonies were detected during the 2018/19 breeding season (Adams et al. 2019). In Victoria no successful breeding has occurred in Western Port and Port Phillip Bay in either the 2017/18 or 2018/19 breeding season (Adams et al. 2019).

In New Zealand, subspecies *davisae* declined to three pairs in 1983 but due to intensive conservation efforts increased to 25-30 birds and 8-10 pairs over four sites in 1998 (Hansen 2006). In 2006 the population had increased to 30-40 individuals and 10 pairs (Parrish and Honnor 1997, Taylor 2000). By 2011, this had increased again to 40-45 individuals and 10 pairs (P-J. Pridham in litt. 2011). As of 2019, the current breeding population has reduced to six pairs.

In New Caledonia, subspecies *exsul* numbers 200 - 400 pairs, but was formerly much more abundant (Barre et al. 2012; BirdLife International 2019). One small population in the Southern Lagoon of New Caledonia may be increasing (Baling et al. 2009).

## 2.6 Ecology

### *Social behaviour*

As with all other terns (Cabot and Nisbet 2013), Australian Fairy Terns are gregarious, gathering together at roost sites both inside and outside the breeding season (Dunlop 2018). Night roosts are generally located on open shoreline features such as sandspits, away from vegetation cover and predators (Dunlop 2018). Some are only occupied during the arrival period whilst others are occupied for most of the breeding season. These roosts may contain birds at a range of ages with the composition changing as the season progresses (Dunlop 2018). Night roosts may include pre- and post-breeding experienced adults, individuals entering their first breeding season, non-breeding individuals in their first summer, and fledglings (Dunlop 2018; J.N. Dunlop pers. obs.).

The social behaviour associated with colony site selection and establishment has not been investigated in Australian Fairy Terns, probably because it is hard to predict when and where it will occur (Dunlop 2018). In other terns that do not have inter-annual nest-site fidelity, courting flocks of reproductively advanced, nuptial plumaged birds commonly occur adjacent to potential colony sites (e.g. Crested Tern - Dunlop 1987, Little Terns - Cramp et al. 1985, Sooty Tern Ashmole 1963, and J.N. Dunlop pers.obs.). Clubs are social roosts only occupied by birds in breeding condition, nuptial plumage, birds courting and ready to breed. Here pair bonds form or reform and these clubs are usually located in close proximity to the breeding site. These areas are critical to the social ecology of the species. Terns in these pre-breeding flocks are typically engaged in bouts of aerial courtship 'social flights' and ground displays or parades at diurnal club sites (Cabot and Nisbet 2013). Pairs form or re-form in these flocks and paired courtship displays frequently follow bouts of group behaviour.

The timing of colony formation and egg-laying is likely dictated by food availability, with colonies forming close to areas of high food abundance (Dunlop 1987). Colonies may occur at the same general location for a series of seasons and then shift (Dunlop 2018). Some observations indicate that a 'neighbourhood' of breeding terns return to the breeding site used in the previous year during the 'clubbing' phase but may then move in a coordinated way to a fresh location (Dunlop 1987, Sooty Tern - J.N. Dunlop pers.obs.). This behavioural pattern may assist in maintaining pair bonds together with providing the opportunity to synchronise timely breeding with neighbours of similar age/experience or quality. Younger, less experienced terns tend to lag in their reproductive cycle, lay later outside the peak foraging window and, as a consequence, have reduced breeding success compared to more experienced pairs (Dunlop 2018).

Male Australian Fairy Terns feed whole fish to their mates in a courtship display that precedes copulation (Serventy et al. 1971). Other inshore feeding terns also carry fish crosswise in their bills to clubs as ornaments in group and paired displays, however in these species courtship feeding is not an obligate prelude to mating (Dunlop 2018). Males also feed their mates whilst they are incubating. It is likely that the ability of male terns to provision females is an important indicator of mate quality and increases breeding performance, as it does in the Common Tern (Nisbet 1973).

### *Breeding*

In Australia, the subspecies breeds between October to February in colonies of various sizes (generally between 2–400 pairs but up to 700 pairs in WA (Dunlop et al. 2015; Dunlop 2018). Colonies can be located on coral shingle on continental islands, or coral cays, on sandy islands and beaches inside estuaries, and open sandy beaches, laying 1 – 2 eggs (rarely 3) in a nest scrape (Higgins and Davies 1996). They nest in clear view of the water and on sites where the substrate is either sandy or on shell-grit and the vegetation sparse.

Incubation duties are shared but females probably spend more time at the nest whilst males actively provision females before and after laying, as is the case with Little Terns (Cramp 1985; Cabot and Nisbet 2013). Incubation lasts for approximately 18 - 22 days (Lindsey 1986; Higgins and Davies 1996). Chicks may be guarded by one parent for the first day or two. However, it is not unusual for chicks to be left alone whilst the adults undertake foraging bouts. Chicks fledge at about 20 days. The success of individual breeding pairs may at least partly depend on the provisioning efficiencies of the males and food availability. Nesting birds are sensitive to disturbance and can become extremely agitated when disturbed by humans or other animals. Females often crouch on the ground; however males have been known to attack intruders (Higgins and Davies 1996; Lindsey 1986).

There is a high natural rate of breeding failure as breeding sites can become inundated during extreme weather events, such as high tides and storm surges or be smothered by wind-blown sand. Strong winds can make foraging very difficult, preventing successful fledging of chicks. Colonies tend to occupy areas rather than fixed sites, and nest sites can be abandoned after one or more years, even if they have been successful (Saunders and de Rebeira 1985).

Interbreeding has been recorded between Fairy Terns and the Little Tern in South Australia (Cox and Close 1977), Victoria (Norman et al. 1996) and NSW (Ross et al. 1999).

### *Feeding*

Australian Fairy Terns hover and then dive into shallow waters in order to catch small baitfish; however they may scavenge from shoals of feeding predatory fish (Higgins and Davies 1996; Dunlop 2018). Australian Fairy Terns feed almost entirely on fish in near-shore waters adjacent to nesting colonies and around island archipelagos (Higgins and Davis 1996). Fish species consumed include Anchovies (*Engraulis australis*), Pilchards (*Sardinops neopilchardus*) and Blue Sprats (*Spratelloides robustus*) (Taylor and Roe 2007). Fairy Terns have been observed opportunistically feeding on small squids during twilight hours (C. N. Greenwell pers. obs).

In south-west Western Australian coastal locations Australian Fairy Terns have been observed carrying Hardyheads (*Pranesus ogilbyi*), Whitebait (*Hyperlophus vittatus*) and Bluesprat up to about 60 mm in length (Dunlop 2018) and Southern Sea Garfish (*Hyporhamphus melanochir*), Snub-nosed Garfish

(*Arrhamphus sclerolepis*) and flying fish (Exocoetidae spp.) up to ~90 mm in length (C. N. Greenwell pers. obs.). At the Abrolhos Islands Australian Fairy Terns handled during banding operations regurgitated Hardyheads between 20 and 50 mm and, surface-schooling, post-larvae of the Black-spot Goatfish (*Parupeneus signatus*), approximately 20-40 mm (Dunlop 2018; J.N. Dunlop pers. obs). In estuarine environments, Gobiidae spp. and Western Hardyheads (*Leptatherina wallacei*) are important dietary constituents (C. N. Greenwell pers. obs). Contemporary dietary studies in eastern Australia are lacking and require further investigation.

## 2.7 Habitat critical to the survival of the Australian Fairy Tern

As noted above, the habitat, or biophysical environment, of the Australian Fairy Tern varies across its range, so it is not possible to generate one detailed description or definition of habitat critical to survival. The habitat critical to the survival of the Australian Fairy Tern may be more usefully defined at a bioregional scale that takes into account the combination of plants, animals, geology, landforms, and climate that is relevant to a geographical unit. However, any categorisation of habitat critical to survival must acknowledge that it exists as a mosaic of coastal habitats and effects of threats.

In general, Australian Fairy Terns utilise a variety of habitats including offshore, estuarine or lacustrine (lake) islands, coastal wetlands, beaches and sand spits. The subspecies migrates within southern and mid-west Western Australia and possibly Tasmania, where they are seen less frequently during the winter months. The Tasmanian and Victorian population may form a single population. The species is more sedentary in the north of Western Australia and in South Australia (Hill et al. 1988). Australian Fairy Terns nest above the high water mark often in clear view of the water and on sites where the substrate is sandy and the vegetation low and sparse. Nests typically consist of a shallow scrape in the sand which is often lined with small shells and vegetation.

As a guide, habitat critical to the survival of the Australian Fairy Tern can be considered to include:

- Any habitat where the species is 'known' or 'likely' to breed or forage as shown in the indicative distribution map (Figure 1).
- Any location outside the above area that may be periodically occupied by Australian Fairy Tern.

Habitat critical to the survival of the Australian Fairy Tern is centred on beaches and offshore islands (for nesting) and near-shore waters (for foraging) and occurs across a wide range of land tenures, including on Indigenous Protected Areas, freehold land, state reserves, and national parks. It is essential that the locations where the species regularly occurs is given the highest protection and conservation measures target these productive habitats. Sympathetic management of buffer areas adjoining nesting and foraging habitats is also important to consider.

Biologically Important Areas for this species occur in Australian Marine Parks, particularly in the South-west and North-west Marine Parks Networks. Under statutory management plans, Australian Marine Parks are managed for the protection and conservation of biodiversity and other natural, cultural and heritage values of marine parks, including protected species.

When considering developments in any part of the tern's range, including in areas where the species 'may occur', surveys for occupancy at the appropriate times (See 2.6 *Ecology*) of the year remain an important tool in establishing the areas of importance for the Australian Fairy Tern. In addition, it is also important to note that the Australian Fairy Tern opportunistically use areas depending on the occurrence of prey species. As such, it is critical to understand the interaction between marine and terrestrial factors and their influence on the areas used by Australian Fairy Terns. Areas that may be important habitat over time might not have birds in any given year. This pattern of habitat use means that recent survey data and historical records need to be considered when assessing the relative importance of a region for the Australian Fairy Tern. Determining limits of acceptable change for trends in occupancy of sites will become an important trigger for determining when absence from an area is of concern and beyond the normal limits of variation.

# THREATS

## 3.1 Historical causes of decline

It is thought that the Australian Fairy Tern has been in decline for at least the past 30 years (Garnett et al. 2011). The decline is most prominent in the eastern subpopulation and is associated with the loss of key breeding habitats and disturbance from a growing human population.

## 3.2 Current threatening processes

The main threat to the subspecies is the disturbance of breeding sites by human activities (including bikes, dogs, horses, drones and vehicles), predation by introduced species and native birds (TSSC 2011; Garnett et al. 2011; Dunlop 2018). The species is also adversely impacted by extreme weather events such as heavy rainstorms and storm surges. It is the species' nesting habitat preferences and behaviours that make the Australian Fairy Tern so susceptible to disturbance, predation and climate variability.

Disturbance may cause direct loss of eggs or the abandonment of nesting sites by the birds resulting in egg-predation or chilling, or overheating of eggs, leading to egg death (Higgins and Davies 1996). Predators of the Australian Fairy Tern include Foxes (*Vulpes vulpes*), Dogs (*Canis familiaris*), Cats (*Felis catus*), Black Rats (*Rattus rattus*), Silver Gulls (*Chroicocephalus novaehollandiae*), Pacific Gulls (*Larus pacificus*), birds of prey and ravens (*Corvus* spp.) (Saunders and de Rebeira 1985; Hill et al. 1988; TSSC 2011). Proximity to roads is also another threat for chicks that are fledging or practising flights.

Australian Fairy Tern nests are a simple scrape in the sand and thus any counterproductive activities in or around the breeding sites are a threat. This includes overgrown vegetation, weed encroachment, housing development, extreme weather events, increased salinity and unsuitable water management in waters surrounding breeding sites (Higgins and Davies 1996; TSSC 2011).

Furthermore, increased salinity in waters adjacent to breeding colonies (particularly in the Coorong, South Australia) can cause local population crashes of prey fish abundance. Nest flooding or exposure to predators can occur due to a respective rise or decline in water levels (TSSC 2011).

In the event of an oil spill, the Australian Fairy Tern could be potentially threatened due to the proximity of the species' breeding habitat to known and potential offshore oil facilities (TSSC 2011).

### 3.2.1 Habitat degradation and loss of breeding habitat

Australian Fairy Terns do not necessarily retain the same nest site from one breeding attempt to the next (Dunlop 2018). However, colonies may establish in the same general locations in consecutive years or re-use certain places intermittently (Dunlop 2018). Shoreline sites are subject to rapid change due to sand erosion or accretion, tidal cycles and sea-levels, beach-wrack movement and deliberate modification. Locations that have been used in the past may be lost, become less attractive to the terns or become subject to increased disturbance or predation (Dunlop 2018). The following of nesting sites may be a strategy to reduce predation risks.

Colony sites that are attractive to breeding pairs may develop naturally or result from coastal development activity including the clearing or loss of dune vegetation, the dumping of dredge spoil or beach-engineering (Dunlop 2018). On occasion, clearing of near coastal areas for development (industrial or residential) can render the area attractive to breeding terns, leading to their rapid colonisation of the site earmarked for development/works. This can lead to conflict between the primary use of the land and its occupation by a threatened species. At Freemantle Ports for example, this led to the creation of an alternative site for breeding terns and this is now one of the most successful breeding locations for the species. Some sites, which are

well above the coastal strand, may become vegetated with native dune vegetation or covered by introduced weeds, making them unusable.

Intervention may be necessary to increase the probability that one or more secure sites will be utilized, or alternatively, to prevent breeding Australian Fairy Terns being attracted to inappropriate locations (Dunlop 2018). Potential breeding sites that result from development footprints or coastal engineering may put nesting terns at risk of breeding failure and increased adult mortality (Dunlop 2018).

In the absence of sufficient protected breeding sites in the local coastal system, steps may have to be taken to enhance the attractiveness of either naturally developing or artificial habitats (Dunlop 2018). This could involve reducing the vegetation cover, contouring the surface to produce low berms or adding shell or limestone pebble material to otherwise visually uniform substrates (Dunlop 2018). Local shell material to enhance preferred nesting sites has been sourced from Pacific Gull feeding stations, and in one case, from the coarse screenings from a marine lime-sand operation. In the absence of cover for the chicks at the margins of a planned nesting area, simple shading 'chick-shelters' can be placed to increase fledging success (Dunlop 2018). These can often be constructed from local rocks or driftwood or purpose built.

In coastal systems where human use pressures now prevent Australian Fairy Terns from breeding successfully, there is growing interest in establishing secure artificial sites (Dunlop 2018). These may be dredge-spoil islands in strategic locations or even floating islands and nesting platforms landscaped to provide breeding habitat. In the absence of legal protections however, even these sites may not be secure from human disturbance.

### **3.2.2 Disturbance**

The presence of people, and/or their dogs, close to an Australian Fairy Tern breeding colony will elicit an anti-predator response. The nest-tending adults will take to the air to avoid disclosing the location of their eggs or young, and will then engage in noisy corporate dives on intruders. Direct physical contact is avoided but the terns will accurately defecate on interlopers or foreign objects within the nesting area.

Ongoing disturbance events during the colony establishment or early-laying period will often lead to the abandonment of the site (a predator avoidance response). Although, relaying a clutch of eggs may occur elsewhere in the coastal system if eggs are lost early in the season. Protracted disturbance later in the nesting cycle may cause unattended eggs or chicks to chill or overheat or starve, leading to egg loss and chick death, or clutches may be buried in moving sand or attract predators. Commensal predators such as gulls, ravens or dogs may follow people (or their rubbish) to colonies and then prey on Australian Fairy Tern eggs or chicks. Gulls and ravens in particular have been known to opportunistically plunder exposed nests during periods of human disturbance.

A number of successful strategies have been employed to try and protect beach nesting birds (including Hooded Plover, Little and Fairy Terns) from human disturbance. These are chick shelters, community education, signage (combined with boundary delineation) and volunteer wardens. However, education does not work on its own without an holistic strategic approach, combining education, on-ground cues (e.g. signs/fences), compliance patrols and reviews of effectiveness/staged responses to reviews.

### **3.2.3 Invasive species**

Most Australian seabirds breed on islands to avoid mammalian predators. However, Australian Fairy Terns also breed at sites along the coastline presumably because they are accessible to near-shore concentrations of small schooling fishes (Dunlop 2018). The breeding strategy adopted by the species (including the regular

shifts in nesting areas) is probably, in part, an adaptation to avoid targeting by land-based predators (Dunlop 2018).

At mainland sites, the major mammalian predators of Australian Fairy Tern nests are foxes, cats, rats and domestic dogs. Baiting programs for foxes, cats and rats can be carried out on the island nature reserves and at remote coastal locations but are generally not an option in public spaces, such as coastal recreation areas, due to the risks to non-target species including pet animals. Soft-jaw traps baited with scent lures (urine or faeces) can be an effective, low risk method, for the targeted removal of foxes and cats in peri-urban and rural areas. These traps are designed for live capture and are not in themselves likely to harm the predator or other non-target animals (e.g. domestic dogs). The use of scent lures rather than food baits reduces their attractiveness to other species.

### **3.2.4 Native wildlife**

Raptors, Silver Gulls and Australian Ravens are the principal avian predators (Dunlop 2018). During the surveillance of potential breeding sites it is useful to detect evidence of predator activity either from direct observation or from tracks (including prepared sand-pads) or using motion-detector cameras (Dunlop 2018). Any anti-predator interventions need to be timely if they are going to be effective.

Managers need to be aware that the presence of people around colonies, including staff and conservation volunteers/wardens, may attract predators (that are also scavengers) to a colony area or provide opportunities for them to locate and plunder the nests (Dunlop 2018). Signs, fence-posts and other structures erected to protect colonies may become observation posts for ravens or birds of prey, increasing the risk of predation (spikes in the top of fence posts can prevent this). Rubbish bins or fish-cleaning stations near beaches with Australian Fairy Tern colonies attract gulls, ravens and rats and should be relocated.

### **3.2.5 Climate variability and change**

Rising sea-levels caused by global warming (thermal expansion and ice-melt) are already forcing changes in shorelines. Coastal engineering works such as sea-walls, groynes, boat harbours, canal developments and reclamation projects also change the pattern of sedimentation and erosion, potentially removing breeding and foraging habitat for Australian Fairy Terns (Dunlop 2018). One result of these changes is that some breeding sites on beaches or sand banks become exposed to tidal flooding (e.g. Peel Estuary) or storm surges (Dunlop 2018). Other sites on accreting shorelines may become vegetated making them unsuitable nesting habitats. Pre-breeding aggregation sites have been abandoned due to the erosion of sand bars (e.g. Penguin Island, Rockingham, WA) and previously secure islands have been connected to the mainland by new sand banks allowing access to domestic dogs and invasive predators such as foxes and Black Rats (e.g. Tern Island in Safety Bay, WA) (Dunlop 2018).

### **3.2.6 Water management and increased salinity**

High water levels in the south-west Western Australian estuaries in recent years have generally reduced the availability of roosting and breeding sites (Dunlop 2018). The drying climate has reduced run-off into some estuaries, leaving entrance blocking sandbars closed throughout the year. The consequence of this is the overfilling of the estuaries including the inundation of roosting and nesting sites on banks and sand-spits, and the loss of connection with the marine food-chain which provides the preferred prey species. This removes roosting, breeding and foraging habitat for Australian Fairy Terns leading to their disappearance from some systems (e.g. Wilson Inlet, WA) (Dunlop 2018).

In the Coorong, South Australia, water management has led to a collapse in the numbers of prey fish, and a subsequent abandonment of traditional breeding sites by Australian Fairy Terns (Garnett et al. 2011). Compounding the loss of foraging habitats, is the lack of secure islands free from predators but close to areas that still support reasonable abundances of small fish (Paton and Rogers 2009). In Victoria, the decommissioning of a saltworks led to the collapse of active water management resulting in salt pans drying out. Once the site of a large breeding colony, Australian Fairy Terns abandoned the site as the previously isolated islands became accessible to mammalian predators and overgrown with vegetation.

### **3.2.7 Pollution**

Australian Fairy Terns locate colonies close to prey resources (generally small schooling fishes) and can often be seen foraging within visual distance of nesting areas (Dunlop 2018). The 'baitfish' often concentrate around estuary mouths where there is enhanced marine productivity from the nutrient plume, or at temperature, salinity or tidal fronts that concentrate plankton. Such areas are also potentially areas of compromised water quality from urban and rural drainage, acid sulphate soils, canals, boat harbours, coastal heavy industries and ports (Dunlop 2018). As such, these areas may be foci for the bio-accumulation of heavy metals and pesticides and the concentration of floating debris.

At present there are no data on the contaminant burden in Australian Fairy Terns from different parts of their breeding range (Dunlop 2018). Little Penguins have a similar diet and foraging habitats to Fairy Terns and these show elevated levels of various contaminants around southwestern Australia, including mercury in Cockburn Sound and selenium in the Albany waterways (Dunlop et al. 2013). At the remote Abrolhos Islands, the binders in fabricated plastics (phthalates) were present in the preen gland secretions of 49 per cent of the Australian Fairy Terns sampled. Phthalates are potent pseudo-oestrogens capable of interfering with sexual development and reproduction.

### **3.2.8 Hybridisation**

Hybridisation has been recorded between Australian Fairy Terns and the Little Tern in South Australia (Cox and Close 1977), Victoria (Norman et al. 1996) and NSW (Ross et al. 1999). Further interbreeding may diminish the genetic distinctiveness of both species (Ross et al. 1999). Interbreeding between Little and Australian Fairy Terns is particularly problematic in NSW where Little Terns are listed as endangered under state legislation. Appropriate management interventions are required to discourage hybridisation, predominantly in NSW.

## **3.3 Threat prioritisation**

Each of the threats outlined above has been assessed to determine the risk posed to the Australian Fairy Tern population using a risk matrix. This, in turn, determines the priority for actions outlined below. The risk matrix considers the likelihood of an incident occurring and the consequences of that incident. Threats may act differently in different parts of the species range and at different times of year, but the precautionary principle dictates that the threat category is determined by the subpopulation at highest risk. Population-wide threats are generally considered to present a higher risk.

The risk matrix uses a qualitative assessment drawing on peer reviewed literature and expert opinion. In some cases the consequences of activities are unknown. In these cases, the precautionary principle has been applied. Levels of risk and the associated priority for action are defined as follows:

Very High - immediate mitigation action required

High - mitigation action and an adaptive management plan required, the precautionary principle should be applied

Moderate – obtain additional information and develop mitigation action if required

Low – monitor the threat occurrence and reassess threat level if likelihood or consequences change

**Table 2.** Risk Prioritisation

Likelihood of occurrence	Consequences				
	Not significant	Minor	Moderate	Major	Catastrophic
Almost certain	Low	Moderate	Very High	Very High	Very High
Likely	Low	Moderate	High	Very High	Very High
Possible	Low	Moderate	High	Very High	Very High
Unlikely	Low	Low	Moderate	High	Very High
Rare or Unknown	Low	Low	Moderate	High	Very High

**Categories for likelihood are defined as follows:**

Almost certain – expected to occur every year

Likely – expected to occur at least once every five years

Possible – might occur at some time

Unlikely – such events are known to have occurred on a worldwide basis but only a few times

Rare or Unknown – may occur only in exceptional circumstances; OR it is currently unknown how often the incident will occur

**Categories for consequences are defined as follows:**

Not significant – no long-term effect on individuals or populations

Minor – individuals are adversely affected but no effect at population level

Moderate – population recovery stalls or reduces

Major – population decreases

Catastrophic – population extinction

**Table 3.** Australian Fairy Tern Residual Risk Matrix

Likelihood of occurrence	Consequences				
	Not significant	Minor	Moderate	Major	Catastrophic
Almost certain			Native wildlife Habitat degradation and loss of breeding habitat	Disturbance Invasive species Climate variability and change	
Likely	Hybridisation		Water management and increased salinity		
Possible		Pollution			
Unlikely					
Rare or Unknown					

## POPULATIONS UNDER PARTICULAR PRESSURE

The eastern subpopulation that occurs in South Australia, Victoria, New South Wales and Tasmania has recorded severe decreases over the last 20 years (Garnett et al. 2011). The eastern subpopulation may be as low as 400 – 660 pairs and is now substantially fragmented. Conservation efforts should focus on the eastern subpopulation to facilitate a positive population trend.

### 4.1 Local conservation strategies

Dunlop (2018) outlines a number of practical solutions for protecting colonies from human encroachment, predators and innovative ways to boost breeding success. One approach to improving Australian Fairy Tern breeding performance within local coastal populations is to encourage the terns to select secure or manageable nesting sites. This can be done using social facilitation techniques that involve the deployment of decoys (models of incubating terns) in configurations that mimic the early stages of colony formation (Dunlop

2018). The effectiveness of the decoy colonies can also be augmented with continuous playback of contact (flock) or advertising calls, although this may not be necessary in all situations.

Decoy colonies have been used successfully on tern species that nest close together and do not retain nest sites between breeding attempts (e.g. Dunlop 1987). Social facilitation methods have been used effectively on Crested, Caspian, Sooty and Least Terns, and will probably be effective for Australian Fairy Terns (Dunlop 2018). The basic preconditions for attracting terns to a preferred location are an appropriate nesting habitat type, overflying terns in breeding condition and sufficient prey resources within the economic foraging range (Dunlop 2018).

Preferred nesting sites for Australian Fairy Terns, whether natural or artificial, need to be identified by experienced personnel. There will need to be a number of alternatives reflecting the variability in productive foraging locations. Local surveillance will be needed to detect which sites may have Australian Fairy Terns in nuptial plumage passing through or utilizing the selected location. These terns will need to be actively foraging within about 2 km of the potential nesting area. If these pre-conditions are met, a decoy colony could be effectively deployed in the preferred nesting area (Dunlop 2018).

Experience suggests that the decoys mimicking incubating birds should be deployed at about double natural colony-spacing (Dunlop 1987). This equates to about 4 m intervals for Australian Fairy Terns (Dunlop 2018). This will encourage the first tern pairs to settle between the decoys in the core of the selected nesting area, reducing the number of nests occupied near the extremities. Signage or other protective measures can then be located with reasonable confidence about the ultimate nest locations (Dunlop 2018).

# RECOVERY PLAN VISION, OBJECTIVES AND STRATEGIES

## Long-term Vision

The Australian Fairy Tern population has increased in size to such an extent that the species no longer qualifies for listing as threatened under any of the *Environment Protection and Biodiversity Conservation Act 1999* listing criteria.

## Recovery Plan Objective

By 2030, sustain a positive population trend in the number of mature individuals of the Australian Fairy Tern in both the eastern and western subpopulations compared to 2020. This will be achieved by implementing the actions set out in this Recovery Plan that minimise threats while protecting the species' habitat throughout its range, generating new knowledge to guide recovery and increasing public awareness.

## Strategies to achieve objectives

1. Manage and protect known Australian Fairy Tern breeding populations at the landscape scale.
2. Develop and apply techniques to measure changes in population trajectory in order to measure the success of recovery actions.
3. Reduce, or eliminate threats at breeding, non-breeding and foraging sites.
4. Improve understanding of breeding, non-breeding and foraging attributes in order to better target management actions and habitat restoration.
5. Engage community stakeholders in Australian Fairy Tern conservation.
6. Coordinate, review and report on recovery process.

# ACTIONS TO ACHIEVE THE SPECIFIC OBJECTIVES

Actions identified for the recovery of the Australian Fairy Tern are described below. It should be noted that some of the objectives are long-term and may not be achieved prior to the scheduled five-year review of the recovery plan. Priorities assigned to actions should be interpreted as follows:

<b>Priority 1:</b>	Taking prompt action is necessary in order to mitigate the key threats to the Australian Fairy Tern and also provide valuable information to help identify long-term population trends.
<b>Priority 2:</b>	Action would provide a more informed basis for the long-term management and recovery of the Australian Fairy Tern.

**Priority 3:** Action is desirable, but not critical to the recovery of Australian Fairy Tern or assessment of trends in that recovery.

**Strategy 1 - Manage and protect known Australian Fairy Tern breeding populations at the landscape scale**

Action	Description	Priority	Performance Criteria	Responsible Agencies and potential partners	Indicative Cost
1a	Identify management units of high conservation priority	1	<ul style="list-style-type: none"> <li>Existing and new information has been reviewed and used to identify important management units that require management intervention</li> </ul>	Recovery Team	\$25,000
1b	Actively use nest protection measures to safeguard nests	1	<ul style="list-style-type: none"> <li>Intervention strategies to protect vulnerable nests from extreme weather, tides and predation have been developed</li> <li>Trials to determine successful techniques have been undertaken</li> <li>Best practice guidelines have been developed and distributed to relevant stakeholders</li> </ul>	State Governments Regional authorities Traditional Owners BirdLife Australia NGOs	\$60,000 pa
1c	Protect and manage areas of 'habitat critical for survival' not currently managed for nature conservation	1	<ul style="list-style-type: none"> <li>Unprotected Commonwealth, state and privately owned land in areas of 'habitat critical to the survival' for Australian Fairy Terns is identified</li> <li>Management plans have been developed and implemented to maximise conservation values of the identified sites</li> <li>Consideration given to formal protection for sites where appropriate (i.e. through new conservation reserves,</li> </ul>	Australian Government State Governments NGOs	Core government business

6c	Submit annual reports on progress against recovery actions	1	<ul style="list-style-type: none"> <li>The Recovery Team has submitted annual reports each year in accordance with the national reporting framework</li> </ul>	Recovery Team	Core government business
6d	Review the recovery plan five years after making	1	<ul style="list-style-type: none"> <li>In consultation with relevant stakeholders, a five review of the recovery plan has been endorsed by the Recovery Team</li> </ul>	Recovery Team	\$10,000
6e	Facilitate knowledge exchange and awareness between Australian, New Zealand and New Caledonian Fairy Tern land managers, researchers and decision makers	1	<ul style="list-style-type: none"> <li>A communication network between interested stakeholders has been established</li> <li>Meetings between site managers have occurred at least biennially to share knowledge and experience</li> <li>A researcher network has been established and exchange visits have occurred between Fairy Tern populations</li> </ul>	Recovery Team	\$30,000

# DURATION AND COST OF THE RECOVERY PROCESS

It is anticipated that the recovery process will not be achieved prior to the scheduled five year review of the recovery plan. The *Recovery Plan for the Australian Fairy Tern* (date) will therefore remain in place until such time as the Australian populations of Fairy Tern have improved to the point at which the populations no longer meet threatened species status under the EPBC Act.

The cost of implementation of this plan should be incorporated into the core business expenditure of the affected organisations, and through additional funds obtained for the explicit purpose of implementing this recovery plan. It is expected that state and Commonwealth agencies will use this plan to prioritise actions to protect the species' and enhance its recovery, and that projects will be undertaken according to agency priorities and available resources. In order to maximise the conservation outcomes and cost effectiveness of this plan, it is intended that the recovery actions proposed complement, where possible, those of other protected matters.

**Table 3:** Summary of recovery actions and estimated costs in (\$000's) for the first five years of implementation (these estimated costs do not take into account inflation over time).

Action	Cost					
	Year 1	Year 2	Year 3	Year 4	Year 5	Total
Strategy 1	310,000	285,000	285,000	285,000	285,000	\$1,450,000
Strategy 2	170,000	145,000	145,000	145,000	145,000	\$750,000
Strategy 3	610,000	610,000	635,000	660,000	610,000	\$3,125,000
Strategy 4	375,000	250,000	250,000	250,000	250,000	\$1,375,000
Strategy 5	125,000	125,000	125,000	125,000	125,000	\$625,000
Strategy 6	10,000	0	10,000	0	20,000	\$40,000
<b>TOTAL</b>	<b>\$1,600,000</b>	<b>\$1,415,000</b>	<b>\$1,450,000</b>	<b>\$1,465,000</b>	<b>\$1,435,000</b>	<b>\$7,365,000</b>

## EFFECTS ON OTHER NATIVE SPECIES AND BIODIVERSITY BENEFITS

Reducing anthropogenic impacts to coastal and marine habitats, supporting work to reduce disturbance and the adverse impacts of invasive species, will likely benefit other listed threatened and migratory species, such as Hooded Plover, Little Tern and migratory shorebirds such as the critically endangered Eastern Curlew and Curlew Sandpiper. Implementation of the recovery plan will also have positive outcomes for other marine and coastal species and listed ecological communities through improving habitat quality.

## SOCIAL AND ECONOMIC CONSIDERATIONS

The major economic impact of this recovery plan will be on those who require approval to remove or modify Australian Fairy Tern habitat and are prevented from doing so, or are required to modify their proposal by a consent authority. As habitats critical to the survival of the species' are identified, there is potential for developments to be restricted under the EPBC Act development assessment and approval process. This may include increased costs due to the assessment processes, requirement to provide offsets to secure or rehabilitate habitat, or for other threat mitigation work.

Restrictions on further development of coastal habitat will impact on some landowners, land managers and developers. These restrictions may not significantly impact agricultural or aquaculture industries since many of the suitable areas have already been developed and the remaining critical habitats are generally located on offshore islands, protected conservation areas and remote locations. These areas are, therefore, relatively less attractive for further development.

Localised, short-term, impacts may occur in areas where nest protection measures are implemented around breeding birds. Temporary fencing to delineate a safe distance from a nesting colony may be required to protect vulnerable eggs and chicks from human disturbance and off-leash dogs. Such structures may restrict access to small areas of beach and cause a minor inconvenience to beach visitors during the Australian Fairy Tern breeding season.

A large network of community volunteers across Australia actively participate in BirdLife Australia coordinated annual surveys for migratory shorebirds and beach nesting birds. Involvement can provide social benefits with community members and engaged groups having a sense of achievement, inclusion, community spirit and pride whilst gaining enjoyment and appreciation of their surrounding natural environment. The community education components of the program also promote community ownership, provide community support and encourage active involvement in protecting local natural resources. In Western Australia, a network of over 300 land managers and citizen scientists regularly contribute information on the movement of banded birds and breeding activities.

In addition, there is the potential for economic gains through ecotourism ventures, nature tours and holiday accommodation operators in areas where the Australian Fairy Tern can reliably be seen. Additional social benefits include encouraging passive recreation, appreciation of natural aesthetic values and increased awareness and appreciation of Indigenous cultural values.

## AFFECTED INTERESTS

Organisations likely to be affected by the actions proposed in this plan include: government agencies (Commonwealth, state and territory, local), particularly those involved with coastal environments and

conservation programs; Indigenous land and sea management groups (including ranger programmes); researchers; bird watching groups; conservation groups; wildlife interest groups; 4WD and fishing groups; environmental consulting companies; tourism operators; industry and commercial bodies; and, proponents of coastal development in the vicinity of important habitat. However, this list should not be considered exhaustive, as there may be other interest groups that may like to be included in the future or need to be considered when specialised tasks are required.

The following table lists some of the interest groups, how they could contribute to the success of the plan and the potential benefits/impacts that may emerge from the Plan's implementation:

<b>Interest Group</b>	<b>Contribution</b>	<b>Impacts/Benefits</b>
Australian Government	Responsible for development, coordination and evaluation of the plan. Responsible for implementation of the plan in Commonwealth areas. Subject to available resources, providing financial support for implementation of the plan.	Informed decision making regarding the EPBC Act referral and assessment process. Greater ability to deliver on domestic and international obligations with regard to biodiversity conservation. Increased knowledge of the Australian Fairy Tern and their habitats – increased exchange of information between decision makers and the community.
State and territory government agencies	Contributing to the development of the plan. Potential implementation of the plan within jurisdictional boundaries.	Greater ability to deliver on state obligations with regard to biodiversity conservation. Increased knowledge of the Australian Fairy Tern and their habitats – increased exchange of information.
Local Government	Contributing to the development of the plan and taking the plan into consideration when reviewing planning schemes. Potential implementation of on ground activities within jurisdictions.	Increased knowledge of the Australian Fairy Tern and their habitats – increased exchange of information. Enhanced ability to deliver obligations with regard to biodiversity conservation. Supports local tourism industry.
Natural Resource Management (NRM) regional bodies	Integrating the plan into NRM regional plans. Opportunity to deliver on-ground activities.	Increased awareness of regional importance of important habitat sites. Informing managers of biodiversity values. Opportunity to seek funding for conservation projects under biodiversity conservation programs.
Land councils and Traditional Owners Including those that have co-management or sole management responsibilities for important habitats.	Contributing to the development of the plan and development and implementation of site management plans – research and monitoring activities – contributing traditional knowledge.	Increased knowledge of the Australian Fairy Tern and their habitats – increased exchange of information. Opportunity to seek funding for conservation projects and achieve ownership of projects. Develop research partnerships with scientists and the community.
Conservation Groups	Contributing to the implementation and evaluation of the plan, particularly in conducting research and monitoring programs – implementing on-ground activities.	Opportunity to seek funding for conservation and awareness projects under biodiversity conservation programs. Greater coordination of targeted conservation projects. Delivering on charitable/not-for-profit goals benefiting the public.

<b>Interest Group</b>	<b>Contribution</b>	<b>Impacts/Benefits</b>
Conservation Council of Western Australia (WA Fairy Tern Conservation Group)	Provision of expert advice on Australian Fairy Tern and their biology, ecology and conservation. Contributing to the implementation and evaluation of the plan, particularly in conducting research and monitoring programs – implementing on-ground activities.	Monitoring of Australian Fairy Tern populations and success of conservation actions. Opportunity to seek funding for conservation and awareness projects under biodiversity conservation programs. Greater coordination of targeted conservation projects.
Australasian Seabird Group / BirdLife Australia	Provision of expert advice on Australian seabirds and their biology, ecology and conservation. Contributing to the implementation and evaluation of the plan, particularly in conducting research and monitoring programs – implementing on-ground activities.	Monitoring of seabird populations and success of conservation actions. Opportunity to seek funding for conservation and awareness projects under biodiversity conservation programs. Greater coordination of targeted conservation projects.
Community and Special Interest groups	Contributing to the plan and volunteering for conservation activities – implementing on-ground activities.	More Australian Fairy Terns to enjoy. Opportunity to participate in conservation projects.
Researchers	Contributing to the implementation and evaluation of the plan.	Increased exchange of information – opportunity to seek funding for research. Opportunity to establish collaborations within Australia and internationally.
Recreational users of sites – beach users, 4WD groups, personal watercraft (jet skis etc.) users, dog walkers, recreational fishers, horse groups, field and game groups.	Contributing to the development of the plan.	Some leisure activities that affect important habitat sites may need to be managed. These groups will be one of the main recipients for education and awareness activities that focus on how they may continue their activities and contribute to the conservation of seabirds at the same time.
Landholders	Contributing to the development and implementation of the plan.	Potential land use impacts. These groups will be the target of education and awareness activities. Particularly on how site management plans may be implemented by landholders. Opportunity to build incentives into the plan for landholders to comply with recommendations. Enhance certainty with regard to EPBC referrals.
Commercial users of sites or surrounding area – aquaculture, salt mining, commercial fisheries, farmers (surrounding land use), airports, maritime ports, renewable energy, tourism operators	Contributing to the plan and implementing measures that minimise the impact of their operations on seabirds.	These groups will also be one of the main recipients for education and awareness activities, although theirs will focus on minimising the impacts of their operations on the Australian Fairy Tern and the habitats on which they depend. Enhance certainty with regard to EPBC referrals.

## CONSULTATION

The *Recovery Plan for the Australian Fairy Tern* has been developed through extensive consultation with a broad range of stakeholders. The consultation process brought together key species experts and conservation managers, from a range of different organisations, to categorize ongoing threats to the Australian Fairy Tern, and identify knowledge gaps and potential management options. Consultation included representatives from government agencies, non-government organisations, researchers and local community groups. During the

drafting process the Department of the Environment and Energy (Cwlth) continued to work closely with key stakeholders.

Notice of the draft plan was made available for public comment for three months between [DATE] and [DATE]. Any comments received that were relevant to the survival of the species were considered by the Threatened Species Scientific Committee as part of its assessment process.

## ORGANISATIONS/PERSONS INVOLVED IN EVALUATING THE PERFORMANCE OF THE PLAN

This plan should be reviewed no later than five years from when it was endorsed and made publicly available. The review will determine the performance of the plan and will be coordinated by the Department of the Environment and Energy, in association with relevant Australian and state government agencies and key stakeholder groups such as non-governmental organisations, local community groups and scientific research organisations.

Key stakeholders who may be involved in the review of the performance of the *Recovery Plan for the Australian Fairy Tern*, include organisations likely to be affected by the actions proposed in this plan and are expected to include:

### **Australian Government**

Department of the Environment and Energy

### **State/territory governments**

Department of Planning and Environment (NSW)

Department of Environment, Land, Water and Planning (Vic)

Department of Environment and Water (SA)

Department of Primary Industries, Parks, Water and Environment (Tas)

Department of Biodiversity, Conservation and Attractions (WA)

Natural resource management bodies in coastal regions

Local government in coastal regions

### **Non-government organisations**

BirdLife Australia

Conservation Council of Western Australia (WA Fairy Tern Conservation Group)

Australasian Seabird Group

Local conservation groups

Local communities

Indigenous communities

Universities and other research organisations

Industry

Recreational sports and associations

Recreational fishers and associations

Recreational boaters
